

Project Design Phase Solution Architecture

Date	30 September 2026
Team ID	SWTID-2026-2452
Project Name	Import Data using Transform Maps (Spreadsheet)
Maximum Marks	4 Marks

Solution Architecture:

1. This solution loads employee data from a spreadsheet into ServiceNow accurately and without duplicates. An admin uploads employee_data.xlsx (Employee ID, Name, Email, Dept, Location) through System Import Sets > Load Data, and the rows land in a temporary Import Set staging table.
2. A Transform Map then maps the source fields to the target fields. It uses Coalesce on Employee ID to find existing records, so people already in the table are updated rather than duplicated. The Transform Engine runs the transform, with optional onBefore and onComplete scripts, and inserts or updates the records in the Target Table (u_employee).
3. Each run writes counts of inserted, updated, ignored, and error rows to Transform History / Error Log. The admin then checks the final data in List View and Reports.
4. **Key benefits:** staged data can be reviewed before it reaches the target table, the field mapping is visible in one place, and the process can be repeated for every new spreadsheet.
